Some combinatorial number theory problems over finite valuation rings

Pham Van Thang       Le Anh Vinh

Abstract

Let $R$ be a finite valuation ring of order $q^r$. In this paper we generalize and improve several well-known results, which were studied over finite fields $\mathbb{F}_q$ and finite cyclic rings $\mathbb{Z}/p^r\mathbb{Z}$, in the setting of finite valuation rings.

1 Introduction

1.1 Dot-product congruence classes of simplices

The Erdős distance problem asks for the minimal number of distinct distances determined by a finite point set in $\mathbb{R}^d$, $d \geq 2$. This problem in the Euclidean plane has recently been solved by Guth and Katz [15]. They showed that a set of $n$ points in $\mathbb{R}^2$ has at least $cn/\log n$ distinct distances. For the latest developments on the Erdős distance problem in higher dimensions, see [20, 28], and the references contained therein. Many related problems has been studying in recent years. A classical result due to Furstenberg, Katznelson and Weiss ([14]) states that if $E \subset \mathbb{R}^2$ of positive upper Lebesgue density, then for any $\delta > 0$, the $\delta$-neighborhood of $E$ contains a congruent copy of a sufficiently large dilate of every three-point configuration. An example of Bourgain ([6]) showed that it is not possible to replace the thickened set $E_\delta$ by $E$ for arbitrary three-point configurations. In the case of $k$-simplex, that is the $k+1$ points spanning a $k$-dimensional subspace, by using Fourier techniques, Bourgain ([6]) showed that a set $E$ of positive upper Lebesgue density always contains a sufficiently large dilate of every non-degenerate $k$-point configuration where $k < d$. In [24, 25], Akos Magyar considered this problem over the integer lattice $\mathbb{Z}^d$. In particular, he showed that a set of positive density will contain a congruent copy of every large dilate of a non-degenerate $k$-simplex where $d > 2k + 4$.

Let $\mathbb{F}_q$ be a finite field of order $q$ with $q = p^n$ for some prime $p$ and positive integer $r$. We say that two $k$-simplices in $\mathbb{F}_q^d$ with vertices $(x_1, \ldots, x_{k+1})$, $(y_1, \ldots, y_{k+1})$ are in a congruence class if the following condition satisfies

$$||x_i - x_j|| = ||y_i - y_j||, \quad 1 \leq i, j \leq k + 1. \quad (1.1)$$

Hart and Iosevich [17] made the first investigation on counting the number of congruence classes of simplices determined by a point set in $\mathbb{F}_q^d$. More precisely, they proved that
if $|E| \gg q^{\frac{kd}{2} + \frac{k}{2}}$ with $d \geq \binom{k+1}{2}$, then $E$ contains a copy of all $k$-simplices with non-zero edges. Several progress on improving this exponent have been made in recent years, for instance, Chapman et al. [11] indicated that one can get a positive proportion of all $k$-simplices in $F_q^d$ under the condition $|E| \gg q^{\frac{d-k}{k+1}}$, and Bennett et al. [4] improved this condition to $q^{d-\frac{d-k}{k+1}}$. Here, and throughout, $X \ll Y$ means that there exists $C > 0$ such that $X \leq CY$, and $X = o(Y)$ means that $X/Y \to 0$ as $q \to \infty$, where $X, Y$ are viewed as functions in $q$.

A variant of this problem was studied by the second listed author [35] with the condition (1.1) is replaced by

$$x_i \cdot x_j = y_i \cdot y_j, \quad 1 \leq i, j \leq k+1.$$ (1.2)

In this case, we say that two $k$-simplices $(x_1, \ldots, x_{k+1})$ and $(y_1, \ldots, y_{k+1})$ are in a dot-product congruence class.

The author of [35] proved that if $|E| \gg q^{\frac{d-k}{d}}$, then the number of dot-product congruence classes of $k$-simplices in $E$ is at least $(1 - o(1))q^{\binom{k+1}{2}}$. This is also an extension of Theorem 1.4, and is the best known result so far. We remark here that the condition (1.1) is equivalent to the fact that there exist $\theta \in O(d, F_q)$ (orthogonal group in $F_q^d$) and $z \in F_q$ so that $z + \theta(x_i) = y_i$ for $i = 1, 2, \ldots, k+1$. From this fact, the authors of [11] used ingenious arguments by combining elementary results from group action theory and Fourier analytic methods to get the threshold $q^{d-\frac{d-k}{k+1}}$. However, this approach does not work for the case of dot-product congruence classes of simplices, since we can not guarantee that there exist $\theta \in O(d, F_q)$ and $z \in F_q$ so that $z + \theta(x_i) = y_i$ for $i = 1, 2, \ldots, k+1$ when two simplices are in a dot-product congruence class.

For the case $k = 1$ and $d = 2$, it has been shown that if $|E| \gg q^{1/3}$, then the number of congruence classes of 1-simplices in $E$ (distinct distances) is at least $\gg q$. However, for the dot-product case, the best known exponent on the cardinality of $E$ to get $\gg q$ dot-product congruence classes of 1-simplices in $E$ (distinct dot product values) is $q^{3/2}$. If we assume that any line passing through the origin contains at most $|E|^{1/2}$ points, then the exponent $q^{1/3}$ also holds for the dot-product problem, see [18, 19] for more details. For general cases, improving the threshold $q^{3/2}$ to $q^{4/3}$ is still an open question.

Let $\mathcal{R}$ be a finite valuation ring of order $q^r$, where $q = p^n$ is an odd prime power. Throughout, $\mathcal{R}$ is assumed to be commutative, and to have an identity. Let us denote the set of units, non-units in $\mathcal{R}$ by $\mathcal{R}^*, \mathcal{R}^0$ respectively. Note that finite fields and finite cyclic rings are special cases of finite valuation rings.

The initial result on the dot product problem in the setting of finite valuation rings was given by Nica in [26]. The precise statement is as follows.

**Theorem 1.1 (Nica, [26]).** Let $\mathcal{E}, \mathcal{F}$ be two sets in $\mathcal{R}^d$. For any $\lambda \in \mathcal{R}^*$, let $N_\lambda(\mathcal{E}, \mathcal{F})$ be the number of pairs $(a, b) \in \mathcal{E} \times \mathcal{F}$ satisfying $a \cdot b = \lambda$. Then we have the following estimate

$$\left| N_\lambda(\mathcal{E}, \mathcal{F}) - \frac{|\mathcal{E}||\mathcal{F}|}{q^d} \right| \leq q^{(d-1)(r-1)/2} \sqrt{|\mathcal{E}||\mathcal{F}|}. $$
Theorem 1.1 implies that if $|\mathcal{E}| |\mathcal{F}| \geq q^{d(2r-1)+1}$, then for any $\lambda \in \mathcal{R}^*$, the equation $a \cdot b = \lambda$ is solvable with $a \in \mathcal{E}, b \in \mathcal{F}$.

Motivated by this result, in this paper we prove the following result on the number of dot-product congruence classes of $k$-simplices over finite valuation rings.

**Theorem 1.2.** Let $\mathcal{R}$ be a finite valuation ring of order $q^*$. Given a set $\mathcal{E} \subseteq \mathcal{R}^d$. Suppose that

$$|\mathcal{E}| \gg q^{\frac{(d-1)(2r-1)+r(k+1)}{2}}.$$ 

Then the number of dot-product congruence classes of $k$-simplices in $\mathcal{E}$ is at least $(1 - o(1))q^{r(k+1)}$.

### 1.2 An improvement on the number of triangle areas

For $\mathcal{E} \subseteq \mathbb{F}_q^d$, we define

$$V_d(\mathcal{E}) := \left\{ \det (x^1 - x^{d+1}, \ldots, x^d - x^{d+1}) : x^1 \in \mathcal{E}, \ 1 \leq i \leq d + 1 \right\}$$

as the set of $d$-dimensional volumes determined by $\mathcal{P}$, and the set of pinned volumes at a point $z \in \mathcal{E}$

$$V_d^z(\mathcal{E}) := \left\{ \det (x^1 - z, \ldots, x^d - z) : x^i \in \mathcal{E}, \ 1 \leq i \leq d \right\}.$$  

In [22], Iosevich, Rudnev, and Zhai showed that if $|\mathcal{E}| \geq 64 q \log q$, then there exists a point $z \in \mathcal{E}$ such that $|V_d^z(\mathcal{E})| \geq q/2$. Note that if we take $\mathcal{E}$ being a set of all points on a line, then there is no non-zero triangle area determined by points in $\mathcal{E}$. Thus this result is sharp up to a factor of $64 \log q$.

Note that a construction in Corollary 2.4 in [19] implies that if $|\mathcal{E}| = o(q^{3/2})$, then there exists $z \in \mathcal{E}$ such that $|V_d^z(\mathcal{E})| = o(q)$. Thus Iosevich et al.’s result can not be improved to say that one gets a positive proportion of the areas from any fixed vertex. The interested reader can find more related discussions in [22].

The finite cyclic ring analogue of this problem is recently investigated by Yazici [36]. In particular, she proved that for $\mathcal{E} \subseteq \mathbb{Z}/p^r\mathbb{Z}$, if $|\mathcal{E}| \geq p^{2r-1/2}$ then $|V_2^z(\mathcal{E})| \geq \frac{p^r}{4} - \frac{1}{p} - 1$. This implies that if $r = 1$, Yazici’s bound is weaker than that of [22]. In this section, we will give an improvement of this result in the setting of finite valuation rings.

**Theorem 1.3.** Let $\mathcal{R}$ be a finite valuation ring of order $q^*$. Let $\mathcal{E}$ be a set of points in $\mathcal{R}^2$. If $q^{2r-1} = o(|\mathcal{E}|)$, then there exists $z \in \mathcal{E}$ such that $|V_2^z(\mathcal{E})| = (1 - o(1))q^r$.

Theorem 1.3 implies that when $\mathcal{R}$ is a finite field, i.e. $r = 1$, in order to get $(1 - o(1))q$ distinct areas we only need the condition $q = O(|\mathcal{E}|)$. This means that we can chop off the logarithmic term in Iosevich et al.’s result. When $\mathcal{R}$ is a finite cyclic ring, i.e. $q$ is a prime $p$, the bound $p^{2r-\frac{1}{2}}$ in [36] is decreased to $p^{2r-1}$.

We remark here that if $\mathcal{E} = \{(x, y) : x, y \in \mathcal{R}^0\}$, then $|\mathcal{E}| = q^{2r-2}$. One can check that $V_2(\mathcal{E}) \subseteq \mathcal{R}^0$, therefore $|V_2(\mathcal{E})| = o(q^r)$. Thus there is a gap between $q^{2r-2}$ and $q^{2r-1}$ for $r \geq 2$. From this construction, we conjecture that the condition on the size of $\mathcal{E}$ can be improved to $q^{2r-2+\epsilon}$ for any $\epsilon > 0$. 

}\text{Page 3}
By using inductive arguments, one can obtain a similar result for higher dimensional cases, which is also a generalization of the main result in \[33\].

**Theorem 1.4.** Let \( \mathcal{R} \) be a finite valuation ring of order \( q^r \), and let \( \mathcal{E} \) be a set of points in \( \mathcal{R}^d \). If \( q^r - 1 \cdot q^{(d-1)} = o(|\mathcal{E}|) \), then there exists a point \( z \in \mathcal{E} \) such that \( |V_z^2(\mathcal{E})| = (1 - o(1))q^r \).

### 1.3 An improvement on permanents of matrices

Let \( M \) be an \( k \times k \) matrix. The permanent of \( M \) is defined by

\[
\text{Per}(M) := \sum_{\sigma \in S_k} \prod_{i=1}^k a_{i\sigma(i)}.
\]

For \( \mathcal{E} \subseteq \mathbb{F}_q^k \), let \( M_k(\mathcal{E}) \) denote the set of \( k \times k \) matrices with rows in \( \mathcal{E} \), and \( P_k(\mathcal{E}) = \{ \text{Per}(M) : M \in M_k(\mathcal{E}) \} \). In the setting of finite fields, the second listed author [34] proved that for \( \mathcal{E} \subseteq \mathbb{F}_q^k \), if \( |\mathcal{E}| \gg q^{\frac{k}{2} + \frac{1}{k}} \) then \( \mathbb{F}_q \setminus \{0\} \subseteq P_k(\mathcal{E}) \). He also indicated that this result is sharp up to a factor of \( k \), for instance, \( |\{x \in \mathbb{F}_q^k : x_1 = 0\}| = q^{k-1} \), and \( P_k(\{x \in \mathbb{F}_q^k : x_1 = 0\}) = \{0\} \). In the case when \( \mathcal{E} \) is the Cartesian product of sets, the author of [34] obtained an improvement. Namely, he showed that for \( \mathcal{A} \subseteq \mathbb{F}_q^k \), if \( |\mathcal{A}| \gg q^{\frac{k}{2} + \frac{1}{k}} \) then \( \mathbb{F}_q \setminus \{0\} \subseteq P_k(\mathcal{A}^k) \). The author of [34] also made a conjecture that the exponent \( q^{k/2 + 1/k} \) can be decreased to \( q^{k/2 + \epsilon} \) for any \( \epsilon > 0 \), when \( k \) is sufficiently large.

By employing the same techniques, a similar result was obtained in the setting of finite cyclic rings \( \mathbb{Z}/p^r\mathbb{Z} \) in [32]. The author of [32] showed that for any \( \mathcal{A} \subseteq \mathbb{Z}/p^r\mathbb{Z} \), if

\[
|\mathcal{A}| \gg rp^{r-\frac{1}{2} + \frac{1}{2k}},
\]

then \( (\mathbb{Z}/p^r\mathbb{Z})^* \subseteq P_k(\mathcal{A}^k) \) with \( \gcd(k,p^r) = 1 \), where \( (\mathbb{Z}/p^r\mathbb{Z})^* \) is the set of all units in \( \mathbb{Z}/p^r\mathbb{Z} \).

In this paper, we are able to improve the threshold \( q^{r-\frac{1}{2} + \frac{1}{2k}} \) to \( q^{(k-1)(2r-1)+r \over 2k-1} \) to get a positive proportion of permanents in a more general setting.

**Theorem 1.5.** Let \( \mathcal{R} \) be a finite valuation rings of order \( q^r \), and \( k \) be an integer with \( \gcd(k,q^r) = 1 \). For any \( \mathcal{A} \subseteq \mathcal{R} \), if

\[
|\mathcal{A}| \gg q^{(k-1)(2r-1)+r \over 2k-1},
\]

then \( |P_k(\mathcal{A}^k)| = (1 - o(1))q^r \).

### 1.4 Monochromatic sum-product

For \( A_1, A_2 \subseteq \mathbb{F}_p \), where \( p \) is a prime, Shkredov [29] showed that \( |A_1||A_2| \geq 20p \), then there exist \( x, y \in \mathbb{F}_p \) such that \( x + y \in A_1, x \cdot y \in A_2 \). Cilleruelo [10] extended this result to arbitrary finite fields \( \mathbb{F}_q \) of \( q \) elements using Sidon sets as follows.
Theorem 1.6 (\cite{10}). For any $X_1, X_2 \subseteq \mathbb{F}_q$ of cardinality $|X_1||X_2| > 2q$, there exist $x, y \in \mathbb{F}_q$ such that $x + y \in X_1, x \cdot y \in X_2$.

In this section, we extend Theorem 1.6 to the setting of finite valuation rings.

Theorem 1.7. Let $R$ be a finite valuation ring of order $q^r$. For any $X_1, X_2 \subseteq R^*$ of cardinality

$$|X_1||X_2| > \frac{q^{4r-1}}{(q^r - q^{r-1})^2},$$

there exist $x, y \in R^*$ such that $x + y \in X_1$ and $x \cdot y \in X_2$.

The rest of this paper is organized as follows: in Section 2, we give the definition and some properties of finite valuation rings. Some tools from spectral graph theory are mentions in Section 3. The proofs of Theorems 1.2, 1.3, 1.5, and 1.7 are given in Sections 4-7.

2 Preliminaries

We say that a ring $R$ is local if $R$ has a unique maximal ideal that contains every proper ideal of $R$. $R$ is principal if every ideal in $R$ is principal. The following is the definition of finite valuation rings taken from \cite{16}.

Definition 2.1. Finite valuation rings are finite rings that are local and principal.

Throughout, rings are assumed to be commutative, and to have an identity. Let $R$ be a finite valuation ring, then $R$ has a unique maximal ideal that contains every proper ideals of $R$. This implies that there exists a non-unit $z$ called uniformizer in $R$ such that the maximal ideal is generated by $z$. Throughout this paper, we denote the maximal ideal of $R$ by $(z)$. Moreover, we also note that the uniformizer $z$ is defined up to a unit of $R$.

There are two structural parameters associated to $R$ as follows: the cardinality of the residue field $F = R/(z)$, and the nilpotency degree of $z$, where the nilpotency degree of $z$ is the smallest integer $r$ such that $z^r = 0$. Let us denote the cardinality of $F$ by $q$. In this note, $q$ is assumed to be odd, then 2 is a unit in $R$.

If $R$ is a finite valuation ring, and $r$ is the nilpotency degree of $z$, then we have a natural valuation

$$\nu : R \to \{0, 1, \ldots, r\}$$

defined as follows: $\nu(0) = r$, for $x \neq 0$, $\nu(x) = k$ if $x \in (z^k) \setminus (z^{k+1})$. We also note that $\nu(x) = k$ if and only if $x = uz^k$ for some unit $u$ in $R$. Each abelian group $(z^k)/(z^{k+1})$ is a one-dimensional linear space over the residue field $F = R/(z)$, thus its size is $q$. This implies that $|(z^k)| = q^{r-k}$, $k = 0, 1, \ldots, r$. In particular, $|z| = q^{r-1}$, $|R| = q^r$ and $|R^*| = |R| - |(z)| = q^r - q^{r-1}$, (for more details about valuation rings, see \cite{11, 5, 13}, and \cite{26}). The following are some examples of finite valuation rings:

1. Finite fields $\mathbb{F}_q$, $q = p^n$ for some $n > 0$. 

2. Finite rings $\mathbb{Z}/p^r\mathbb{Z}$, where $p$ is a prime.

3. $\mathcal{O}/(p^r)$ where $\mathcal{O}$ is the ring of integers in a number field and $p \in \mathcal{O}$ is a prime.

4. $\mathbb{F}_q[x]/(f^r)$, where $f \in \mathbb{F}_q[x]$ is an irreducible polynomial.

3 Tools from spectral graph theory

We say that a bipartite graph $G = (A \cup B, E)$ is \textit{biregular} if in both of its two parts, all vertices have the same degree. If $A$ is one of the two parts of a bipartite graph, we write $\text{deg}(A)$ for the common degree of the vertices in $A$. Label the eigenvalues so that $|\lambda_1| \geq |\lambda_2| \geq \cdots \geq |\lambda_n|$. Note that in a bipartite graph, we have $\lambda_2 = -\lambda_1$. In this paper, we denote the adjacency matrix of $G$ by $M$. The following is the expander mixing lemma for bipartite graphs. The reader can find a detailed proof in [12].

\textbf{Lemma 3.1.} Suppose $G$ is a bipartite graph with parts $A, B$ such that the vertices in $A$ all have degree $a$ and the vertices in $B$ all have degree $b$. For any two sets $X \subset A$, and $Y \subset B$, the number of edges between $X$ and $Y$, $e(X, Y)$, satisfies

$$\left| e(X, Y) - \frac{a}{|B|}|X||Y| \right| \leq \lambda_3 \sqrt{|X||Y|},$$

where $\lambda_3$ is the third eigenvalue of $G$.

The following theorem is an analogue of [2, Theorem 9.2.4].

\textbf{Theorem 3.2.} Let $G = (A \cup B, E)$ be a bipartite graph as in Lemma 3.1 and $U, V$ two subsets in $A, B$, respectively. Then we have the following estimate

$$\sum_{u \in U} \left( N_V(u) - \frac{a}{|B|}|V| \right)^2 \leq \lambda_3^2 |V|,$$

where $N_V(u) = N(u) \cap V$, and $N(u)$ is the set of all neighbors of $u$.

\textbf{Proof.} Let denote $c = |V|/|B|$, and $x$ be a vector, where $x_i = I_{i \in V} - c1_B$. We note that $\sqrt{a}1_A \pm \sqrt{b}1_B$ are eigenvectors corresponding to $\lambda_1, \lambda_n$. It follows from the definition of $x$ that $< x, 1_A > = 0$ and $< x, 1_B > = 0$. Then $x \in W$, and $||Mx||^2 \leq \lambda_3^2 ||x||^2$. We note that

$$< Mx, Mx > = \sum_{u \in A} \left( N_V(u) - \frac{a|V|}{|B|} \right)^2,$$

and $||x||^2 = (1 - c)^2 |V| + (|B| - |V|)c^2 = (1 - c)|V| < |V|$, then the lemma follows from the fact that

$$\sum_{u \in U} \left( N_V(u) - \frac{a|V|}{|B|} \right)^2 \leq \sum_{u \in A} \left( N_V(u) - \frac{a|V|}{|B|} \right)^2.$$ 

$\square$

6
3.1 Product graphs over finite valuation rings

We define the product graphs $P_{q,r}(R) = (A \cup B, E)$ over finite valuation rings $R$ as follows: $A = B = R^d \setminus (R^0)^d$, and there is an edge between $x \in A$ and $y \in B$ if and only if $x \cdot y = 1$. The spectrum of this graph was given by Nica [26].

**Theorem 3.3** (Nica, [26]). The cardinality of each vertex part of $P_{q,r}(R)$ is $q^{dr} - q^{d(r-1)} = (1 - o(1))q^{dr}$, and $\deg(A) = \deg(B) = q^{(d-1)r}$. The third eigenvalue of $P_{q,r}(R)$ is at most $\sqrt{q^{(d-1)(2r-1)}}$.

3.2 Erdős-Rényi graphs over finite valuation rings

For any $x \in R^d \setminus (R^0)^d$, we denote $[x]$ the equivalence class of $x$ in $R^d \setminus (R^0)^d$, where $x, y \in R^d \setminus (R^0)^d$ are equivalent if and only if $x = ty$ for some $t \in R^*$. Let $E_{q,d}(R)$ denote the Erdős-Rényi bipartite graph $(A \cup B, E)$ whose vertices in each part are the points of the projective space over $R$, where two vertices $[x]$ and $[y]$ are connected if and only if $x \cdot y = 0$. We have the following theorem on the spectrum of $E_{q,d}(R)$.

**Theorem 3.4** (Nica, [26]). The cardinality of each vertex part of $E_{q,d}(R)$ is $q^{d-1}(r-1)(q^d - 1)/(q - 1)$, and $\deg(A) = \deg(B) = q^{(d-2)(r-1)(q^d-1) - 1}/(q - 1)$. The third eigenvalue of $E_{q,d}(R)$ is at most $\sqrt{q^{(d-2)(2r-1)}}$.

As an application of the Erdős-Rényi graph $E_{q,2d}(R)$, we obtain the following theorem which is a generalization of [22] Theorem 9. Some of its applications over finite fields can be found in [19], [22].

**Theorem 3.5.** Let $F$ and $G$ be subsets in $R^d$. Suppose that $F \cap (R^0)^d = \emptyset$. Let, for $t \in R$,

$$\nu(t) := |\{(x, y) \in F \times G : x \cdot y = t\}|,$$

where $x \cdot y = x_1y_1 + \cdots + x_dy_d$. Then

$$\sum_{t \in R} \nu(t)^2 \leq \frac{|F|^2|G|^2}{q^r} + q^{(d-1)(2r-1)}|F||G| \cdot \max_{x \in R^d \setminus (R^0)^d} |F \cap l_x|,$$

where

$$l_x := \{sx : s \in R^*\},$$

with $x \in R^d \setminus (R^0)^d$.

**Proof.** For any pair of points $(a, b) \in R^d \times R^d$, we define

$$p_{a,b} := (a_1, \ldots, a_d, b_1, \ldots, b_d),$$

and

$$U := \{p_{x,-t} : (x, t) \in F \times G\} \subseteq R^{2d}, V := \{p_{y,z} : (y, z) \in G \times F\} \subseteq R^{2d}.$$
Since $F \cap (\mathcal{R}^0)^d = \emptyset$, $U$ and $V$ are sets of points in $\mathcal{R}^{2d} \setminus (\mathcal{R}^0)^{2d}$. It follows from the definition of $\nu(t)$ that $\sum_{t \in \mathcal{R}} \nu(t)^2$ is the number of quadruples $(x, y, z, t) \in F \times G \times F \times G$ satisfying $x \cdot y = z \cdot t$. It is clear that if $x \cdot y = z \cdot t$, then there is an edge between two vertices $[p_{x-t}]$ and $[q_{x-t}]$ in the Erdős-Rényi graph $\mathcal{E}_{q,2d}(\mathcal{R})$. However, we can not make sure that the number of edges between $[U] := \{[u] : u \in U\}$ and $[V] := \{[v] : v \in V\}$ in the Erdős-Rényi graph $\mathcal{E}_{q,2d}(\mathcal{R})$ is an upper bound for the sum $\sum_{t \in \mathcal{R}} \nu(t)^2$, since there might exist two points in $U$ determining the same congruence class, i.e. the same vertex in the Erdős-Rényi graph $\mathcal{E}_{q,2d}(\mathcal{R})$, for example $u \in U$ and $\lambda u \in U$ with $\lambda \in \mathcal{R}^* \setminus \{1\}$.

Thus we will partition $U$ and $V$ to subsets such that no two points in each subset determine the same vertex in the Erdős-Rényi graph.

Since $m = \max_{x \in \mathcal{R}^d \setminus (\mathcal{R}^0)^d} |F \cap l_x|$, we can partition $U$ into $m$ subsets $U_1, \ldots, U_m$ of distinct vertices of the Erdős-Rényi graph $\mathcal{E}_{q,2d}(\mathcal{R})$. Similarly, we also can partition $V$ into $m$ subsets $V_1, \ldots, V_m$ of distinct vertices of the Erdős-Rényi graph $\mathcal{E}_{q,2d}(\mathcal{R})$. Then, it is clear that

$$\sum_{t \in \mathcal{R}} \nu(t)^2 \leq \sum_{i,j} e(U_i, V_j) = \sum_{j=1}^{m} e(U_1, V_j) + \cdots + \sum_{j=1}^{m} e(U_m, V_j).$$

On the other hand, for each $1 \leq i \leq m$, it follows from Lemma 3.1 and Theorem 3.4 that

$$\sum_{j=1}^{m} e(U_i, V_j) \leq \frac{|U_i||V|}{q^r} + q^{(d-1)(2r-1)} \sqrt{|U_i||V_1| + \cdots + |V_m|} \leq \frac{|U_i||V|}{q^r} + \sqrt{mq^{(d-1)(2r-1)}} \sqrt{|U_i||V|},$$

where the second inequality follows from the Cauchy-Schwarz inequality. Thus

$$\sum_{t \in \mathcal{R}} \nu(t)^2 \leq \frac{|U||V|}{q^r} + q^{(d-1)(2r-1)} m \sqrt{|U||V|}.$$

From the definitions of $U$ and $V$, we get $|U| = |F||G|$ and $|V| = |F||G|$. Therefore the theorem follows.

Now we prove the following theorem that will be used many times in this paper.

**Theorem 3.6.** Let $F$ and $G$ be subsets in $\mathcal{R}^2$. Suppose that $m = \max_{x \in \mathcal{R}^2 \setminus (\mathcal{R}^0)^2} |F \cap l_x|$, then we have

$$|\{x \cdot y : x \in F, y \in G\}| = (1 - o(1))q^r,$$

when $mq^{(d-1)(2r-1)+r} = o(|F||G|)$.

**Proof.** We first have

$$|\{x \cdot y : x \in F, y \in G\}| = |\{t : \nu(t) > 0\}|,$$
and
\[ \sum_{t \in \mathbb{R}} \nu(t) = |F||G|. \]

On the other hand, let
\[ T = |\{(x_1, y_1, x_2, y_2) \in F \times G \times F \times G : x_1 \cdot y_1 = x_2 \cdot y_2\}|, \]
which implies that
\[ T = \sum_{t \in \mathbb{R}} \nu(t)^2. \]

It follows from the Cauchy-Schwarz inequality that
\[
|\{t : \nu(t) > 0\}| \sum_{t \in \mathbb{R}} \nu(t)^2 \geq \left(\sum_{t \in \mathbb{R}} \nu(t)\right)^2.
\]

Therefore, we obtain
\[
|\{t : \nu(t) > 0\}| \geq \frac{|F|^2|G|^2}{T}. \tag{3.1}
\]

On the other hand, it follows from Theorem \[3.5\] that
\[
T \leq \frac{|F|^2|G|^2}{q^r} + mq^{(d-1)(2r-1)}|F||G|. \tag{3.2}
\]

Putting (3.1) and (3.2) together gives us
\[
|\{x \cdot y : x \in F, y \in G\}| = (1 - o(1))q^r,
\]
when \(mq^{(d-1)(2r-1)+r} = o(|F||G|)\). This concludes the proof of the theorem.

\[\square\]

4 Proof of Theorem \[1.2\]

A graph \(G = (V, E)\) is called an \((n, d, \lambda)\)-graph if it is \(d\)-regular, has \(n\) vertices, and the second eigenvalue of \(G\) is at most \(\lambda\). Suppose that a graph \(G\) is edge-colored by a set of finite colors. We say that \(G\) is an \((n, d, \lambda)\)-colored graph if the induced subgraph of \(G\) on each color is an \((n, d(1 + o(1)), \lambda)\)-graph. In [35], the second listed author proved that any large induced subgraph of an \((n, d, \lambda)\)-colored graph contains almost all possible colorings of small complete subgraphs.

**Theorem 4.1.** ([35, Theorem 2.7]) For any \(t \geq 2\). Let \(G = (V, E)\) be an \((n, d, \lambda)\)-colored graph, and let \(m < n\) such that \(m \gg \lambda(n/d)^{1/2}\). Suppose that the color set of \(\mathcal{C}\) has cardinality \(|\mathcal{C}| = (1 - o(1))n/d\), then for every subset \(U \subset V\) with cardinality \(m\), the induced subgraph \(G\) on \(U\) contains at least \((1 - o(1))|\mathcal{C}|^{\lceil t/2 \rceil}\) possible colorings of \(K_t\).
Let $\mathcal{C} = \mathcal{R}^*$, we now define a graph $G(\mathcal{R})$ as follows: the vertex set of $G(\mathcal{R})$ is $\mathcal{R}^d$ and the edge between $x$ and $y$ is colored by the $\beta$-color with $\beta \in \mathcal{C}$, if and only of $x \cdot y = \beta$.

One can follow the proof of [35, Theorem 2.7] step by step by using Lemma 3.1, Theorem 3.2, and Theorem 3.3 to get a version of Theorem 4.1 for $G(\mathcal{R})$ as follows.

**Theorem 4.2.** For any $t \geq 2$, and for every subset $U \subset V(G(\mathcal{R}))$ of cardinality $m \gg \frac{q^{(d-1)(2r-1)+rt}}{2}$, the induced subgraph of $G(\mathcal{R})$ on $U$ contains at least $(1 - o(1))q^{r\left(\frac{k}{2}\right)}$ possible colorings of $K_t$.

We are now ready to prove Theorem 1.2.

**Proof of Theorem 1.2.** Since $|E| \gg \frac{q^{(d-1)(2r-1)+rt}}{2}$, it follows from Theorem 4.2 that the induced subgraph $G(\mathcal{R})$ on $E$ contains at least $(1 - o(1))q^{r\left(\frac{k}{2}\right)}$ possible colorings of $K_k+1$. Moreover, each coloring is corresponding to a dot-product congruence class, thus the number of dot-product congruence classes of $k$-simplices in $E$ is at least $(1 - o(1))q^{r\left(\frac{k}{2}\right)}$. This ends the proof of the theorem.

5 Proofs of Theorems 1.3 and 1.4

Before giving a proof of Theorem 1.3, we have the following observation: Since the area of triangle is invariant under translations, we can assume that $0 \in E$, and the formula of area of the triangle formed by three vertices $0, a = (a_1, a_2)$ and $b = (b_1, b_2)$ is $a_1b_2 - a_2b_1$.

Let $S$ be the set of triangles in $E$ which share a common vertex at $0$. Then the number of distinct areas of triangles in $S$ is at least the cardinality of $E \cdot E' := \{x \cdot y : x \in E, y \in E'\}$,

where $E' = \{(y, -x) : (x, y) \in E\}$.

A result of Nica in [26], i.e. Theorem 1.1, states that if $|E||E'| > q^{4r-1}$, then $|E \cdot E'| \gg q^r - q^{r-1}$. It is clear that $|E| = |E'|$. Thus if $|E| > q^{2r-\frac{1}{2}}$, then the number of distinct areas of triangles in $E$ is at least $q^r - q^{r-1}$. In fact, the result of Nica [26] gives us even more information, for instance, the number of triangles of area $t \in \mathcal{R}^*$ is at least $(1 - o(1))\frac{|E'|^2}{q^r}$ when $q^{2r-\frac{1}{2}} = o(|E|)$.

However, in order to decrease from the exponent $q^{2r-\frac{1}{2}}$ to $q^{2r-1}$, we need to use more complicated and tricky arguments. First we need to prove the following lemma.

**Lemma 5.1.** Let $\mathcal{R}$ be a finite valuation ring of order $q^t$, and let $E$ be a set of $8q^{2r-1}$ points in $\mathcal{R}^2$. Then there exists a point $z$ of $E$ such that $z$ is contained in at least $q^r/8$ lines, and each of these lines passes through at least $q^{r-1} + 1$ points from $E$.

**Proof of Lemma 5.1.** To prove Lemma 5.1, we make use of the following theorem on the number of incidences between points and lines in $\mathcal{R}^2$, where a line in $\mathcal{R}^2$ is of the form $ax + by + c = 0$, $(a, b, c) \in \mathcal{R}^3 \setminus (\mathcal{R}^0)^3$. 

Theorem 5.2. Let $\mathcal{R}$ be a finite valuation ring of order $q^r$, $\mathcal{E}$ be a set of points in $\mathcal{R}^2$ and $\mathcal{L}$ be a set of lines in $\mathcal{R}^2$. Then the number of incidences between the point set $\mathcal{E}$ and the line set $\mathcal{L}$, denoted by $I(\mathcal{E}, \mathcal{L})$, satisfies

$$\left| I(\mathcal{E}, \mathcal{L}) - \frac{|\mathcal{E}| |\mathcal{L}|}{q^r} \right| \leq q^{(2r-1)/2} \sqrt{|\mathcal{E}||\mathcal{L}|}.$$

Proof. We identify each point $(x_1, x_2) \in \mathcal{E}$ with a vertex $[x_1, x_2, 1]$ of the Erdős-Rényi graph $E_{q,3}(\mathcal{R})$. Let $\mathcal{E}'$ be the set of corresponding vertices. Similarly, we identify each line $ax + by = c$ in $\mathcal{L}$, $(a, b, c) \notin (\mathcal{R}^0)^3$, with a vertex $[a, b, -c]$ of the Erdős-Rényi graph $E_{q,3}(\mathcal{R})$. Let $\mathcal{L}'$ be the set of corresponding vertices. Then $\mathcal{E}'$ and $\mathcal{L}'$ are sets of distinct vertices with $|\mathcal{E}'| = |\mathcal{E}|$ and $|\mathcal{L}'| = |\mathcal{L}|$.

It is easy to see that the number of incidences between $\mathcal{E}$ and $\mathcal{L}$ equals the number of edges between $\mathcal{E}'$ and $\mathcal{L}'$ in the Erdős-Rényi graph $E_{q,3}(\mathcal{R})$. It follows from Lemma 3.1 and Theorem 3.4 that

$$\left| I(\mathcal{E}, \mathcal{L}) - \frac{|\mathcal{E}| |\mathcal{L}|}{q^r} \right| \leq q^{(2r-1)/2} \sqrt{|\mathcal{E}||\mathcal{L}|}.$$

This concludes the proof of the theorem. \hfill \square

The following is a corollary of Theorem 5.2.

Corollary 5.3. Let $\mathcal{R}$ be a finite valuation ring of order $q^r$, and let $\mathcal{E}$ be a set of $3q^{2r-1}$ points in $\mathcal{R}^2$. Then the number of distinct lines spanned by $\mathcal{E}$ containing at least $q^{r-1} + 1$ points from $\mathcal{E}$ is at least $q^{2r}/4$.

Proof. Let $\mathcal{L}_1$ be the set of lines in $\mathcal{R}^2$ such that each line contains at most $q^{r-1}$ points from $\mathcal{E}$. We now show that $|\mathcal{L}_1| \leq 3q^{2r}/4$. Indeed, we first have $I(\mathcal{E}, \mathcal{L}_1) \leq q^{r-1} |\mathcal{L}_1|$, and it follows from Theorem 5.2 that

$$I(\mathcal{E}, \mathcal{L}_1) \geq \frac{|\mathcal{E}| |\mathcal{L}_1|}{q^r} - q^{(2r-1)/2} \sqrt{|\mathcal{E}||\mathcal{L}_1|} \geq 3q^{r-1} |\mathcal{L}_1| - \sqrt{3} q^{2r-1} \sqrt{|\mathcal{L}_1|}.$$

This implies that

$$2q^{r-1} |\mathcal{L}_1| \leq \sqrt{3} q^{2r-1} \sqrt{|\mathcal{L}_1|}.$$

Thus, we obtain

$$|\mathcal{L}_1| \leq \frac{3q^{2r}}{4}.$$

On the other hand, the number of lines of the form $y = ax + b$ in $\mathcal{R}^2$ is $q^{2r}$, then the number of lines of the form $y = ax + b$ containing at least $q^{r-1} + 1$ points from $\mathcal{E}$ is at least $q^{2r}/4$. Since any two lines in $\mathcal{R}^2$ have at most $q^{r-1}$ points in common, these lines are distinct. This completes the proof of the corollary. \hfill \square

We are ready to give a proof of Lemma 5.1.
Proof of Lemma 5.1. Let $\mathcal{L}$ be the set of lines in $\mathbb{R}^2$ such that each line in $\mathcal{L}$ contains at least $q^{r-1} + 1$ points from $\mathcal{E}$. It follows from Corollary 5.3 that $|\mathcal{L}| \geq q^{2r}/4$. From the lower bound of Theorem 5.2, we have if $|\mathcal{E}|\mathcal{L}| \geq 2q^{4r-1}$, then $I(\mathcal{E}, \mathcal{L}) \geq |\mathcal{E}|\mathcal{L}|/q^r$. Thus it implies that $I(\mathcal{E}, \mathcal{L}) \geq q^{3r-1}$. Therefore, by the pigeon-hole principle, there exists a point $z \in \mathcal{E}$ such that $z$ is contained in at least $q^r/8$ lines from $\mathcal{L}$, and each of these lines contains at least $q^{r-1} + 1$ points from $\mathcal{E}$.

Proofs of Theorems 1.3 and 1.4:

Proof of Theorem 1.3. Since $|\mathcal{E}| \geq 8q^{2r-1}$, we have $|\mathbb{R}^0|^2 = o\left(|\mathcal{E} \cap \mathbb{R}^2 \backslash (\mathbb{R}^0)^2|\right)$. Thus, without loss of generality, we can assume that $\mathcal{E} \subseteq \mathbb{R}^2 \backslash (\mathbb{R}^0)^2$. Lemma 5.1 implies that there exists a point $z \in \mathcal{E}$ such that $z$ is contained in at least $q^r/8$ lines, and each of these lines passes through least $q^{r-1} + 1$ points from $\mathcal{E}$. We denote the set of these lines by $\mathcal{L}'$.

We now consider the set of triangles in $\mathcal{E}$ which share a common vertex at $z$. Since the area of a triangle is invariant under translations, we assume that $z = 0$, and all lines in $\mathcal{L}'$ are of the form $l_k := \{y = kx\}$ with $k \in \mathbb{R}$. It is easy to see that for a fixed $a \in \mathbb{R}$, the points $(x, ax) \notin l_b$ for all $b \neq a$ and $x \in \mathbb{R}^*$. Thus, we can choose $q^r/8$ points of $\mathcal{E}$ from the lines in $\mathcal{L}'$ such that no two points belong to the same line. Let $F$ be the set of such points, and $G := \{(-p_2, p_1): (p_1, p_2) \in \mathcal{E}\}$. Then the number of distinct areas of triangles formed by three vertices $(0, a, b) \in \{0\} \times F \times G$ is the cardinality of the set $F \cdot G = \{a \cdot b: a \in F, b \in G\}$.

Applying Theorem 3.6 with $|F| = q^r/8, |G| = 8q^{2r-1}$, $d = 2$, and $m = 1$, we get

$$|F \cdot G| = (1 - o(1))q^r.$$ 

This implies that the number of distinct areas determined by $\mathcal{E}$ is at least $(1 - o(1))q^r$. This concludes the proof of the theorem.

Proof of Theorem 1.4. We prove Theorem 1.4 by induction on $d$. The base case $d = 2$ follows from Theorem 1.3. Suppose that the statement is true for all $2 < i \leq d - 1$, we now show that it also holds for $d$. Indeed, since $|\mathcal{E}| \geq 8q^{r-1}q^{r(d-1)}$, there exists a hyperplane $H_t := \{x \in \mathbb{R}^d: x_d = t\}$ such that $|\mathcal{E} \cap H_t| \geq 8q^{r-1}q^{r(d-2)}$. By induction hypothesis, we have $|V_{d-1}(\mathcal{E} \cap H_t)| \geq q^{r}/2$.

Since $V_d(\mathcal{E})$ is invariant under translations, we can assume that $t = 0$. Moreover, the number of points of $\mathcal{E}$ satisfying $x_d \in \mathbb{R}^0$ is at most $q^{r-1} \cdot q^{r(d-1)}$. Thus, there exists a point $z \in \mathcal{E}$ such that $z_d \in \mathbb{R}^*$. On the other hand, $V_d^*(\mathcal{E})$ are determinants of size $d + 1$ of the form

$$\det \begin{pmatrix} 1 & \cdots & 1 \\ x_1 & \cdots & x_1 \\ \vdots & \ddots & \vdots \\ x_{d-1} & \cdots & x_{d-1} \\ 0 & \cdots & 0 \end{pmatrix} = z_d \cdot \det \begin{pmatrix} 1 & \cdots & 1 \\ x_1 & \cdots & x_1 \\ \vdots & \ddots & \vdots \\ x_{d-1} & \cdots & x_{d-1} \end{pmatrix}.$$ 

This completes the proof of the Theorem 1.4.

\[\square\]
6 Proof of Theorem 1.5

Since \(|A| \gg q^{(k-1)(2r-1)+r} > q^{r-1} = |R^0|\), there exists a unit \(u \in A \cap R^*\). Let \(1 := (1, \ldots, 1) \in R^k\), \(u = (u, \ldots, u) \in R^k\). For any two points \(x, y\) in \(A^k\), let \(M(u, x, y)\) denote the matrix whose rows are \(x, y\) and \((k-2)\) \(u\)'s.

We have

\[
\text{Per}(M(u, x, y)) = u^k \text{Per}(M(1, x/u, y/u)) = u^k \sum_{i=1}^{k} \frac{x_i}{u} \sum_{j \neq i} \frac{y_j}{u}. \tag{6.1}
\]

Thus we are able to reduce the permanent problem to the dot product problem of two following sets:

\[
F := \left\{ \left( \frac{x_1}{u}, \ldots, \frac{x_k}{u} \right) : (x_1, \ldots, x_k) \in A^k \right\},
\]

\[
G := \left\{ \left( \sum_{j \neq 1} y_j/u, \ldots, \sum_{j \neq k} y_j/u \right) : (y_1, \ldots, y_k) \in A^k \right\}.
\]

It is clear that \(|F| = |A|^k\) and \(|G| = |A|^k\) since \(\gcd(k, q^r) = 1\). From (6.1) we get

\[|\text{Per}(M(u, x, y))| = |F \cdot G|,\]

then the theorem follows immediately from Theorem 3.6 with \(m = |A|\).

7 Proof of Theorem 1.7

The proof of Theorem 1.7 is based on the study of the equation \((x_1/2 - z)(x_1/2 + z) = x_2\) where \(x_1 \in X_1, x_2 \in X_2\) and \(z \in X_3\). Here, \(X_3 \equiv R^*\). This equation is equivalent to the equation \((x_1/2)^2 - x_2 = z^2\). We set

\[
A_1 = \{(x_1/2)^2 \mid x_1 \in X_1\}, A_2 = \{-x_2 \mid x_2 \in X_2\},
\]

\[
A_3 = \{z^2 \mid z \in X_3\}, A_4 = \{z^2 \mid z \in X_3\}.
\]

Note that the equation \(x^2 = a^2\) has at most two solutions in \(R\) for any \(a \in R^*\). Thus, we have

\[|A_1| \geq |X_1|/2, |A_2| = |X_2|, |A_3| \geq |X_3|/2, |A_4| \geq |X_3|/2.\]

The equation \((x_1/2)^2 - x_2 = z^2\) has a solution \(x_1 \in X_1, x_2 \in X_2, z \in X_3\) if and only if there exists an edge between two vertex sets \(U := \{[a_3, 1, a_1] : (a_3, 1, a_1) \in A_3 \times \{1\} \times A_1\} \) and \(V := \{[a_4, 1, a_2] : (a_4, 1, a_2) \in A_4 \times \{1\} \times A_2\}\) in the Erdős-Rényi graph \(E_{q,3}(R)\). Therefore, from Lemma 3.3 and Lemma 3.4 that

\[e(U, V) \geq |A_1||A_2||A_3||A_4|/q^r - q^{(2r-1)/2}|A_1||A_2||A_3||A_4|.|A|.
\]

Thus if

\[|X_1|X_2 > q^{4r-1}/(q^{r} - q^{r-1})^2,\]

then \(e(U, V) > 0\), and the theorem follows.
